North American Wetlands Conservation Act Reporting Requirements

This document fulfills the requirements of Section 10 and 16 of the North American Wetlands Conservation Act of 1989.

Sec. 10. REPORT TO CONGRESS.

The Secretary shall report to the appropriate Committees on the implementation of this Act. The report shall include—

(1) a biennial assessment of—

(A) the estimated number of acres of wetlands and habitat for waterfowl and other migratory birds that were restored, protected, or enhanced during such two-year period by Federal, State, and local agencies and other entities in the United States, Canada, and Mexico;

(B) trends in the populations size and distribution of North American migratory birds;

(C) the status of efforts to establish agreements with nations in the western hemisphere pursuant to section 16; and

(D) wetlands conservation projects funded under this Act, listed and identified by type, conservation mechanism (such as acquisition, easement, or lease), location, and duration.

(2) an annual assessment of the status of wetlands conservation projects, including an accounting of expenditures by Federal, State, and other United States entities, and expenditures by Canadian and Mexican sources to carry out these projects.

Sec. 16. OTHER AGREEMENTS.

(a) The Secretary shall undertake with the appropriate officials of nations in the western hemisphere to establish agreements, modeled after the [North American Waterfowl Management] Plan or the [Tripartite] Agreement, for the protection of migratory birds identified in section 13(a)(5) of the Fish and Wildlife Conservation Act of 1980 (16 U.S.C. 2912(a)). When any such agreements are reached, the Secretary shall make recommendations to the appropriate Committees on legislation necessary to implement the agreements.

Migratory Bird Trends [Section 10(1)(B)]

Each year, the U.S. Fish and Wildlife Service, in conjunction with states, the Canadian Wildlife Service, provincial governments, and other partners, conducts breeding-ground surveys to estimate the size of duck breeding populations. Specialized surveys track trends in the populations of other harvested migratory species such as the mourning dove and the American woodcock. The North American Breeding Bird Survey, conducted annually on approximately 2,900 routes in the United States and Canada by thousands of volunteers, is used to follow changes in the distribution and abundance of many other migratory bird species utilizing wetlands and associated habitats.

Habitat conditions at the time of the breeding waterfowl surveys in May of 2004 and 2005 were variable, with some areas improving relative to 2002-2003 conditions and others remaining or becoming increasingly dry.

Wetland conditions in the U.S. portion of the important duck breeding area known as the Prairie Pothole Region were fair to poor due to sustained dry conditions; however, water levels within North Dakota and eastern Montana improved markedly just after the 2005 survey with the onset of well-above average precipitation. Alaska's conditions improved from generally good to excellent. Maine also

continues to have generally good to excellent conditions. Wetland conditions within Canada were also variable, ranging from generally good in the Canadian Parklands and the western Northwest Territories to fair or poor conditions within southern Alberta, the eastern Northwest Territories, and extreme southern sections of Manitoba and Saskatchewan. Within the northern prairie provinces, conditions were generally fair to good.

The total number of ducks surveyed in 2005 was 31.7 million, about 12 percent below the 2003 estimate of 36.2 million. Three of the 10 most common duck species exceeded species-specific North American Waterfowl Management Plan (Plan) goals: gadwall, green-winged teal, and northern shoveler. Mallard, American wigeon, blue-winged teal, northern pintail, redhead, canvasback, and scaup populations are below Plan objective levels. Northern pintail and scaup populations remain depressed and concern lingers about the status of these species. The greater and lesser scaup population estimate was 46 percent below the Plan goal—a new record low estimate. Pintail population estimates were 54 percent below the Plan population goal in 2005.

Most goose populations in North America continue to thrive. Only two show significant declines over the previous 10-year period: the Short Grass Prairie Canada goose population and the Pacific brant population. The Atlantic Canada goose population, of previous concern due to its depressed abundance, has recovered to record-high numbers. The dusky Canada goose population remains a concern, persisting at a low but relatively stable level due to long-term breeding-ground habitat changes. Recent declines in indices of Mid-continent white-fronted geese resulted in more conservative harvest strategies being implemented in 2005. Overabundant goose populations (i.e., several populations of temperate-nesting Canada geese, greater and lesser snow geese, and Ross's geese) continue to impact habitats and human interests. Harvest strategies to reduce the abundance of these populations have been implemented. While these strategies have reduced the populations' rate of growth, some populations may still be increasing. Additional monitoring data is required to determine if these populations can be held in check through the regulatory options pursued thus far.

Between 2004 and 2005, call-count indices of mourning dove populations (doves heard) increased significantly in the Eastern Management Unit; did not change significantly in the Central Unit; and decreased significantly in the Western Unit. Over the past 10 years, no significant trend was indicated for doves heard in either the Eastern or Western Management Unit, whereas the Central showed a significant decline. Over the entire 40-year survey period, all three units have exhibited significant declines. Breeding population indices derived through the American Woodcock Singing-ground Survey in 2005 were unchanged from 2004 for both the Eastern and Central Management Regions. There was not a significant trend in woodcock heard on the survey in either the Eastern or Central Region between 1995 and 2005. This represents the second consecutive year since 1992 that the 10-year trend estimate for either region was not a significant decline. There were significant long-term declines in both regions, however, over the period of 1968 to 2005. If current trends in land-use practices persist, continued long-term population declines are likely. In an effort to halt such declines, the International Association of Fish and Wildlife Agencies has created a Woodcock Task Force to develop a woodcock conservation plan.

Trends of other migratory bird species vary widely. Of all species groups, grassland nesting birds have exhibited the most consistent negative population trends since the late 1960s, with 71 percent of these species showing significant population declines. These patterns can be explained by extensive loss or degradation of grassland habitat from agricultural uses as well as by increases in haying. Restoration of native grasses or planting of dense-nesting cover under the North American Waterfowl Management Plan and funded through the North American Wetlands Conservation Act has produced positive impacts on the density of nesting birds and nest success in the Prairie Pothole Region. These and other critical programs, such as the Conservation Reserve Program and Partners in Flight, provide hope for these beleaguered populations.

As a whole, 36 percent of wetland/open-water-dependent migratory bird species show significant increasing long-term population trends. Fourteen percent of these species exhibit significant declining long-term trends. However, data from the North American Breeding Bird Survey are poor for many of these species, and conclusions must be viewed with caution.

Throughout North America, there are significant decreasing population trends for 37 percent of species breeding in successional or scrub habitats while 30 percent of species breeding in woodland habitats show significant increasing population trends from 1966. However, there are still 36 species that breed in woodland habitats that have been exhibiting significant decreasing population trends over the 39-year period. Population trends for six species breeding in urban habitats are significantly declining over the long term, while three urban-nesting species are significantly increasing across North America.

The above species groups contain short-distance migrants and neotropical migrants. Short-distance migrants breed and winter north of the United States-Mexico border, while neotropical migrants winter south of it. In certain areas where the number of short-distance migrant species is highest, such as the northeast United States, Great Lakes states, and the Canadian prairie, negative population trends predominate for this group. In all, 40 percent of these species exhibit significant decreasing trends. Regional population trends of neotropical migrants are complex and patterns are difficult to discern. Thirty-four percent of neotropical migrant species have exhibited significant negative population trends since the late 1960s.

For many species, the extent to which population trend is driven by the destruction and degradation of wintering habitats south of the United States is unknown. However, it is believed that habitat loss south of the United States border is contributing to the decline of some of these species.

International cooperation is needed to assure the conservation of habitats used by migratory birds throughout their annual cycles. It is through continental programs such as the North American Waterfowl Management Plan and North American Wetlands Conservation Act Grants Program that international cooperation can be fostered.

International Agreements

[Section 10(1)(C)]

No progress has been made to establish agreements with officials of other nations in the Western Hemisphere for the protection of migratory birds.
